SOCE Codebook v0.1

Measurement canon · Social-Ontological Cycle of Exclusion

Luis Bourguet · LabOnt — Centre for Ontology, Università degli Studi di Torino

v0.1.0 · July 2026

Scope and governing sources

This codebook is the operative extraction of the SOCE measurement canon. It is derived from the canonical Spanish-language project documents — chiefly *SOCE · Sistema completo de métricas* (v1.0, June 2026), the *Documento matriz del exoesqueleto*, and the two-module specification — and distils them into the coding scheme an analyst needs to produce a structural signature. The ordinal notation itself is language-independent. Where wording here and in the source documents could be read differently, the source documents govern.

Governing principle. *La IA propone, el humano decide* — the AI proposes, the human decides. The AI handles scale, syntactic consistency and pattern alerting; the human retains interpretive sovereignty, the ethics of diagnosis and control of the fundamental ontology.

0 · The measurement canon

SOCE does not measure exclusion with indices, coefficients or continuous values. It measures through a layered ordinal-nominal notation governed by one invariant rule:

> **The notation describes what is already observed in a diagnosis; it introduces no magnitudes that are not measured. If something cannot be read from an existing diagnosis, it does not enter the notation.**

This rule has an absolute operative consequence: **no ordinal state may ever be averaged, summed or weighted.** The order L < P < D < E is qualitative, not arithmetic — the step from L to P is not necessarily equal to the step from D to E. Assigning numeric weights to qualitative states, or fabricating parameters the referent does not exhibit, is cosmetic formalisation and is explicitly rejected.

Reproducibility is defined as two independent analysts producing the same structural signature Φ on the same case — never as a statistical coefficient. Divergence between analysts is not suppressed by a threshold; it is versioned and graded on the ordinal δ scale (see `protocol/delta_protocol`).

What the metrics deliberately do not do. No SOCE metric produces an exclusion score. Distances between qualitative states are not uniform; a score would aggregate dimensions the system treats as irreducible; and a score would rank persons on a continuum, creating direct algorithmic risk under the EU AI Act. The system produces a topology of processes, not rankings of people.

Where statistics lives. The canon forbids quantification *inside* the signature Φ. It does not forbid statistics in the calibration membrane of the Anchor Set: quantitative corpora may calibrate the boundary between ordinal categories, but the output that enters Φ is always the ordinal descriptor. *Statistics calibrates the rubric; it never contaminates the signature.*

1 · The structural signature Φ = ⟨σ, V, E⟩

Each case is represented by one structural signature: a tuple of three layers, measured separately and never collapsed into a single number.

Layer	Notation	What it measures
σ — node intensity	⟨I, II, III, IV, V⟩ ∈ {L, P, D, E}	The role of each of the five nodes in the case
V — Todorov axes	(ax, px, ep) ∈ {1..5}	Intensity of the treatment of the Other on three independent axes
E — link states	11 links ∈ {·, →, ⇒, →ᵐ, →⁺}	How the cycle flows between the active

		nodes

Diacritics: ⁻ marks weakened intensity within its category (e.g. D⁻); an arrow over a state marks a transition in progress (e.g. D→E).

2 · Layer σ — node intensity

Each node receives one state on a four-value ordinal scale:

Symbol	State	Meaning
L	Latent	The node exists but is not a motor of the cycle
P	Present	The node operates and contributes
D	Dominant	The node is one of the motors of the case
E	Structural	The node is the backbone of the case

Qualitative order: **L < P < D < E**. Never averaged, never summed.

2.1 The five nodes and their anchor sources

Node	Question it answers	Anchor source
I · Documentality	Who counts, in the record? Inscription decides: censuses, acts, statutes, databases	Ferraris
II · Ideological anatomy	What belief system naturalises the exclusion as "what is"? Tuple ⟨C,S,D,G,B,A,P,V,I,O,M⟩; the decisive element is the **A_core**, the non-negotiable nucleus the rest protects	Romero
III · Imagined community	How is the We — and the image of the excluded — fabricated and diffused? Critical variable: **velocity** of reproduction	Anderson
IV · Normative obedience	Why does the norm bind, and how is it obeyed? Act-sources and fact-sources; ten modes of obedience, each with its characteristic fracture	Pegoraro & Rinella
V · Production of the Other	How is the excluded defined, treated and known? Three irreducible axes	Todorov

Symbol collisions (G, V, B appear in more than one node) are resolved by node prefixing — II.G, II.V, II.B — never by tensors.

3 · Layer V — the Todorov axes

The only node with a subvector metric: three simultaneous, independent axes, each ordinal 1–5. **The three axes are never summed or averaged; their dissociation is diagnostic.** Between the planes there are affinities but, in Todorov's terms, no rigorous implication: one cannot be reduced to or predicted from another.

Axis	What it measures	Range
ax — axiological	How the Other is valued	1 = equal · 5 = existential threat
px — praxeological (*the thermometer*)	How the Other is treated	1 = assimilation · 5 = physical elimination
ep — epistemological	How the Other is known	1 = own voice · 5★ = erasure of the Other's own knowledge

The **px** axis carries the full boundary-descriptor rubric (see `anchors/anchor_rubrics`). The marker **ep:5★** flags the erasure of the Other's own knowledge — the level at which resistance takes generations to rebuild. Low px with high ax is the *elite-Other* reading (corpus: MORENA, ax=4, px=2): the Other is valued as a grave threat but not physically eliminated. Averaging the axes would destroy exactly the information that distinguishes τ_3 from τ_1.

4 · Layer E — the links

While σ measures which nodes are active, E measures how they relate: what each node transmits to which, with what intensity, in which direction.

4.1 The five link states

State	Symbol	Meaning
Inactive	·	The link does not operate in this case
Active	→	The link operates
Dominant	⇒	The link carries the causal weight of the case
Modulated	$\rightarrow^{m}$	Operates with a brake (economic limit, institutional fracture, asymmetry)
Accelerant	$\rightarrow^{+}$	Reinforces itself with each iteration

4.2 The catalogue of eleven links

Five canonical links (the spine) and six shortcuts confirmed against the corpus, two of which emerged from extraction itself. The catalogue is **saturated**: no proposed shortcut remained without a documenting case.

Link	What it transfers	Type
I→II	Inscription fixes which categories are available for belief	Canonical
II→III	The A_core supplies the content to diffuse	Canonical
III→IV	The imagined community generates obedience	Canonical
IV→V	Obedience institutionalises the treatment of the Other	Canonical
V→I	The consolidated Other re-inscribes into the record	Canonical (closure)
I→IV	The record coerces obedience without dense ideology	Shortcut (EU 2015)
I→V	De-inscription is already production of the Other	Shortcut (Rohingya)
III→V	Technology produces Others in real time	Shortcut (MORENA, Rohingya)
III→IV	Aesthetic camouflage produces identitarian obedience	Shortcut (AfD/Lukreta)
V→III	The consolidated Other feeds back into imagination	Shortcut
II→I	Ideology rewrites the record (inversion)	Shortcut (MAGA, MORENA)

Each link has a verifiable activation condition; that verifiability is what sustains reproducibility.

4.3 The recursive closure V→I

V→I is not one more step: it is the macro-link that filters, in each iteration, which inscriptions can be updated — only those coherent with the already-consolidated Other. In Onnis's terms this is downward causation: the macro level conditions the micro.

Intervention asymmetry. Before the loop closes, interrupting one link suffices to stop the cycle. After closure, simultaneous multi-node intervention is required: a single-node intervention is absorbed by the others. Apartheid (1994) is the only corpus case successfully interrupted from within, through simultaneous intervention in nodes I, II, III and IV.

5 · Derived metrics

5.1 The topological family τ

The family is read from the configuration of E — which links are active, which is dominant, which are modulated — never from σ. Derivation is **structural comparison against the existing families, not numerical distance**. A case that fits no family is a new type: the signal of a theoretically productive case.

Family	Corpus cases	Defining trait
τ_1 canonical-full	1, 5, 7	All links active, high intensity, I→II as motor
τ_2 braked at IV→V	2, 3	Economic limit modulates obedience→Other; px ≤ 3
τ_3 inversion II→I	9, 10	Ideology rewrites the record; contemporary democracies
puente (skip of II)	4, 6	I⇒V or I⇒IV; dense ideological elaboration is bypassed
aislado (III motor)	8, 11	III⇒IV via aesthetic camouflage; extra-registral actor

Two multiple realisations validate the architecture: **τ_3 = {MAGA, MORENA}** joins a right-wing and a left-wing movement in the same subgraph despite opposed A_cores — structural invariance across ideological sign; **aislado = {AfD/Lukreta, Patriot Front}** joins an electoral party with partial institutional access and an extra-institutional group with none — structural invariance across institutional position. The equivalence is topological, not axiological: identical structure does not imply equivalent gravity, which is read from px and from the presence or absence of internal limits.

5.2 The topological genocide-risk correlate

A second-order metric legible directly from the signature. The two genocidal corpus cases (Nazi, Rohingya) are the only ones in which **no link entering or leaving node V is modulated and the closure V→I is accelerant**. In every other case some link to or from V is braked — by an economic limit, an institutional fracture, or an axiological-praxeological asymmetry.

The full substantive predictor requires co-presence of four conditions: (1) an A_core of inverted causality — the Other is the cause of the ill, not merely its consequence; (2) absence of legal subjecthood of the Other; (3) absence of an economic limit; (4) the V→I acceleration condition. Its precise topological correlate is the absence of any modulation on node-V links combined with accelerant V→I. This is a **correlate read from the signature of a consolidated case, not a predictive instrument**; the prospective module detects tendency and does not forecast outcomes.

5.3 The δ scale — graded divergence

Measures how far apart two signatures produced by different analysts on the same case are. Each grade contains the previous ones ($\delta_0 < \delta_1 < \delta_2 < \delta_3 < \delta_4$): a legitimate ordinal order by inclusion, not a distance metric. Full specification and the operating procedure live in `protocol/delta_protocol`.

6 · Modulated links are the map of fractures

A modulated link ($\rightarrow^m$) is not a failure of the cycle: it is the signal of where resistance can intervene. Reading what brakes what is reading the structure of opportunities for interruption. Together with the characteristic fracture of the dominant obedience mode (Node IV), this is the system's principal practical output.

Version note

v0.1.0 freezes the current canon only. Open analytical flags of the project (recorded in the project flag register) are **not** resolved in this document; any change they produce enters as a versioned release, never as a silent edit.
